I Pandas Introduction

Pandas is a Python library that makes handling tabular data easier. Since we're doing data science - this is something we'll use from time to time!

It's one of three libraries you'll encounter repeatedly in the field of data science:

Pandas

Introduces "Data Frames" and "Series" that allow you to slice and dice rows and columns of information.

NumPy

Usually you'll encounter "NumPy arrays", which are multi-dimensional array objects. It is easy to create a Pandas DataFrame from a NumPy array, and Pandas DataFrames can be cast as NumPy arrays. NumPy arrays are mainly important because of...

Scikit Learn

3

2

20

Υ

Ν

The machine learning library we'll use throughout this course is scikit_learn, or sklearn, and it generally takes NumPy arrays as its input.

So, a typical thing to do is to load, clean, and manipulate your input data using Pandas. Then convert your Pandas DataFrame into a NumPy array as it's being passed into some Scikit_Learn function. That conversion can often happen automatically.

Let's start by loading some comma-separated value data using Pandas into a DataFrame:

```
In [1]: %matplotlib inline
          import numpy as np
          import pandas as pd
          df = pd.read_csv("PastHires.csv")
          df.head()
Out[1]:
                                                              Level of
                                              Previous
                     Years
                                                                           Top-tier
                           Employed?
                                                                                   Interned Hired
                Experience
                                            employers
                                                            Education
                                                                            school
          0
                        10
                                                                  BS
                                                                                Ν
                                                                                         Ν
                                                                                               Υ
                        0
                                   Ν
                                                    0
                                                                  BS
                                                                                Υ
                                                                                         Υ
          1
          2
                         7
                                   Ν
                                                                  BS
                                                                                Ν
                                                                                         Ν
```

head() is a handy way to visualize what you've loaded. You can pass it an integer to see some specific number of rows at the beginning of your DataFrame:

1

MS

PhD

Υ

Υ

Ν

Ν

Ν

| df. | head(10) | | | | | | |
|-----|---------------------|-----------|--------------------|-----------------------|--------------------|----------|-------|
| | Years Experience | Employed? | Previous employers | Level of Education | Top-tier school | Interned | Hired |
| 0 | 10 | Υ | 4 | BS | N | N | , |
| 1 | 0 | N | 0 | BS | Υ | Υ | , |
| 2 | 7 | N | 6 | BS | N | N | - |
| 3 | 2 | Υ | 1 | MS | Υ | N | , |
| 4 | 20 | N | 2 | PhD | Υ | N | - 1 |
| 5 | 0 | N | 0 | PhD | Υ | Υ | , |
| 6 | 5 | Υ | 2 | MS | N | Υ | , |
| 7 | 3 | N | 1 | BS | N | Υ | • |
| 8 | 15 | Υ | 5 | BS | N | N | |
| 9 | 0 | N | 0 | BS | N | N | |

You can also view the end of your data with tail():

| [3]: | df.tail(4) | | | | | | | | | | |
|------|------------|---------------------|-----------|--------------------|-----------------------|--------------------|----------|-------|--|--|--|
| [3]: | | Years Experience | Employed? | Previous employers | Level of Education | Top-tier school | Interned | Hired | | | |
| | 9 | 0 | N | 0 | BS | N | N | N | | | |
| | 10 | 1 | N | 1 | PhD | Υ | N | N | | | |
| | 11 | 4 | Υ | 1 | BS | N | Υ | Υ | | | |
| | 12 | 0 | N | 0 | PhD | Υ | N | Υ | | | |

We often talk about the "shape" of your DataFrame. This is just its dimensions. This particular CSV file has 13 rows with 7 columns per row:

```
In [4]: df.shape
Out[4]: (13, 7)
```

The total size of the data frame is the rows * columns:

```
In [5]: df.size
Out[5]: 91
```

The len() function gives you the number of rows in a DataFrame:

```
In [6]: len(df)
Out[6]: 13
```

If your DataFrame has named columns (in our case, extracted automatically from the first row of a .csv file,) you can get an array of them back:

Extracting a single column from your DataFrame looks like this - this gives you back a "Series" in Pandas:

You can also extract a given range of rows from a named column, like so:

Or even extract a single value from a specified column / row combination:

```
In [10]: df['Hired'][5]
Out[10]: 'Y'
```

To extract more than one column, you pass in a list of column names instead of a single one:

| <pre>In [11]: Out[11]:</pre> | df[['Ye | ears Exper | ience |
|------------------------------|---------|--------------|-------|
| | Year | s Experience | Hired |
| | 0 | 10 | Υ |
| | 1 | 0 | Υ |
| | 2 | 7 | N |
| | 3 | 2 | Υ |
| | 4 | 20 | N |
| | 5 | 0 | Υ |
| | 6 | 5 | Υ |
| | 7 | 3 | Υ |
| | 8 | 15 | Υ |
| | 9 | 0 | N |
| | 10 | 1 | N |
| | 11 | 4 | Υ |
| | 12 | 0 | Υ |

You can also extract specific ranges of rows from more than one column, in the way you'd expect:

Sorting your DataFrame by a specific column looks like this:

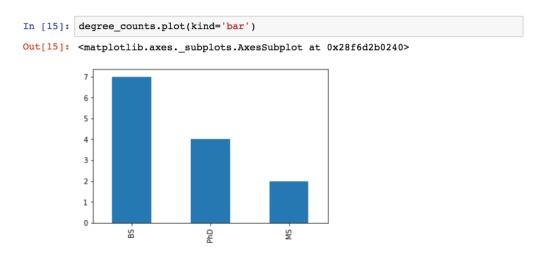

| [13]: | df.sc | ort_values(| ['Years E | xperience']) | | | | | |
|----------|-------|---------------------|-----------|--------------------|-----------------------|--------------------|----------|-------|--|
| Out[13]: | | Years Experience | Employed? | Previous employers | Level of Education | Top-tier school | Interned | Hired | |
| | 1 | 0 | N | 0 | BS | Υ | Υ | Υ | |
| | 5 | 0 | N | 0 | PhD | Υ | Υ | Υ | |
| | 9 | 0 | N | 0 | BS | N | N | N | |
| | 12 | 0 | N | 0 | PhD | Υ | N | Υ | |
| | 10 | 1 | N | 1 | PhD | Υ | N | N | |
| | 3 | 2 | Υ | 1 | MS | Υ | N | Υ | |
| | 7 | 3 | N | 1 | BS | N | Υ | Υ | |
| | 11 | 4 | Υ | 1 | BS | N | Υ | Υ | |
| | 6 | 5 | Υ | 2 | MS | N | Υ | Υ | |
| | 2 | 7 | N | 6 | BS | N | N | N | |
| | 0 | 10 | Υ | 4 | BS | N | N | Υ | |
| | 8 | 15 | Υ | 5 | BS | N | N | Υ | |
| | 4 | 20 | N | 2 | PhD | Υ | N | N | |
| | | | | | | | | | |

You can break down the number of unique values in a given column into a Series using value_counts() - this is a good way to understand the distribution of your data:

```
In [14]: degree_counts = df['Level of Education'].value_counts()
degree_counts

Out[14]: BS     7
    PhD     4
    MS     2
    Name: Level of Education, dtype: int64
```

Pandas even makes it easy to plot a Series or DataFrame - just call plot():

II. Series

The first main data type we will learn about for pandas is the Series data type. Let's import Pandas and explore the Series object.

A Series is very similar to a NumPy array (in fact it is built on top of the NumPy array object). What differentiates the NumPy array from a Series, is that a Series can have axis labels, meaning it can be indexed by a label, instead of just a number location. It also doesn't need to hold numeric data, it can hold any arbitrary Python Object.

Let's explore this concept through some examples:

```
In [2]: import numpy as np import pandas as pd
```

1. Creating a Series

You can convert a list, numpy array, or dictionary to a Series:

```
In [3]: labels = ['a','b','c']
my_list = [10,20,30]
arr = np.array([10,20,30])
d = {'a':10,'b':20,'c':30}
```

Using Lists

```
In [4]: pd.Series(data=my_list)
Out[4]: 0
            10
            20
            30
        dtype: int64
In [5]: pd.Series(data=my_list,index=labels)
Out[5]: a
            10
             20
        dtype: int64
In [6]: pd.Series(my_list,labels)
Out[6]: a
            10
            20
           30
        dtype: int64
```

NumPy Arrays

Dictionary

```
In [9]: pd.Series(d)
Out[9]: a   10
        b   20
        c   30
        dtype: int64
```

2. Data in Series

A pandas Series can hold a variety of object types:

3. Using an index

The key to using a Series is understanding its index. Pandas makes use of these index names or numbers by allowing for fast look ups of information (works like a hash table or dictionary).

Let's see some examples of how to grab information from a Series. Let us create two sereis, ser1 and ser2:

```
In [12]: ser1 = pd.Series([1,2,3,4],index = ['USA', 'Germany','USSR', 'Japan'])
In [13]: ser1
Out[13]: USA
                    1
         Germany
                    2
         USSR
                    3
         Japan
         dtype: int64
In [14]: ser2 = pd.Series([1,2,5,4],index = ['USA', 'Germany','Italy', 'Japan'])
In [15]: ser2
Out[15]: USA
                    1
         Germany
                    2
         Italy
         Japan
         dtype: int64
In [16]: ser1['USA']
Out[16]: 1
```

Operations are then also done based off of index:

```
In [17]: ser1 + ser2

Out[17]: Germany 4.0

Italy NaN
Japan 8.0
USA 2.0
USA NaN
dtype: float64
```

Let's stop here for now and move on to DataFrames, which will expand on the concept of Series!

III. DataFrames

DataFrames are the workhorse of pandas and are directly inspired by the R programming language. We can think of a DataFrame as a bunch of Series objects put together to share the same index. Let's use pandas to explore this topic!

1. Selection and Indexing

Let's learn the various methods to grab data from a DataFrame

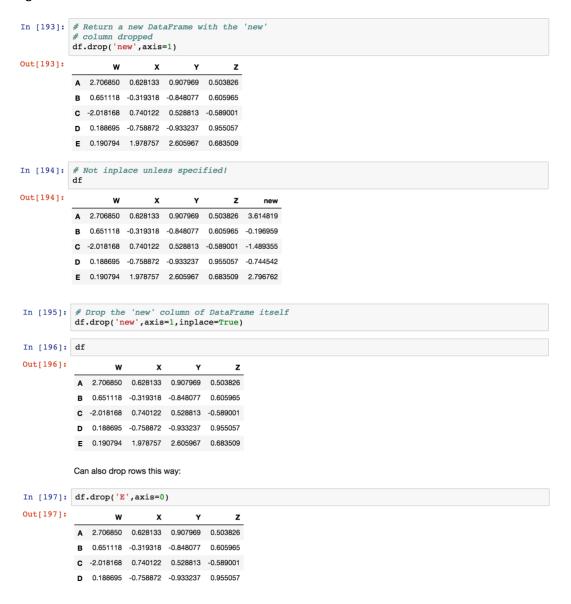

```
In [187]: df['W']
Out[187]: A
                2.706850
                0.651118
              -2.018168
           C
              0.188695
               0.190794
          Name: W, dtype: float64
In [188]: # Pass a list of column names
df[['W','z']]
Out[188]:
           A 2.706850 0.503826
            B 0.651118 0.605965
           C -2.018168 -0.589001
           D 0.188695 0.955057
           E 0.190794 0.683509
In [189]: # SQL Syntax (NOT RECOMMENDED!)
           df.W
Out[189]: A
               2.706850
               0.651118
           С
              -2.018168
               0.190794
           Name: W, dtype: float64
```

DataFrame Columns are just Series

```
In [190]: type(df['W'])
Out[190]: pandas.core.series.Series
```

Creating a new column:

Removing Columns

Can also drop rows this way:

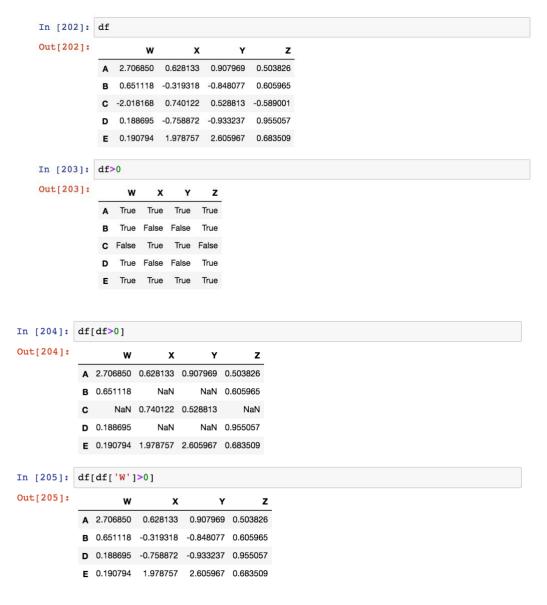

Selecting Rows

Or select based off of position instead of label

Selecting subset of rows and columns

2. Conditional Selection

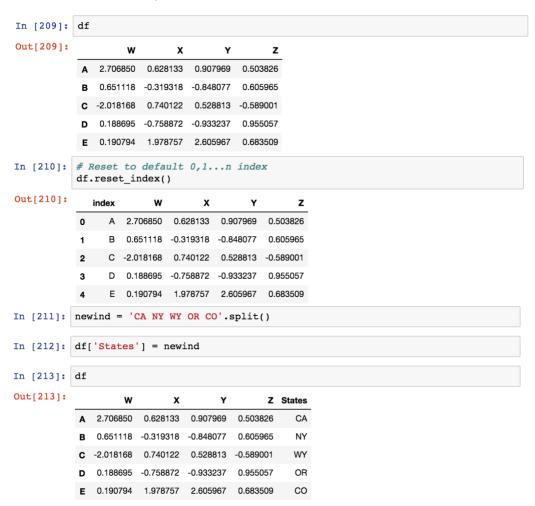

An important feature of pandas is conditional selection using bracket notation, very similar to numpy:

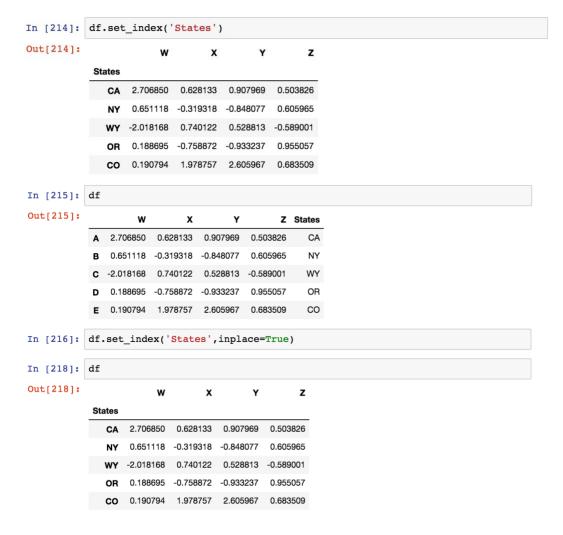

For two conditions you can use | and & with parenthesis:

3. More Index Details

Let's discuss some more features of indexing, including resetting the index or setting it something else. We'll also talk about index hierarchy!

4. Multi-Index and Index Hierarchy

Let us go over how to work with Multi-Index, first we'll create a quick example of what a Multi-Indexed DataFrame would look like:

```
In [253]: # Index Levels
           outside = ['G1','G1','G1','G2','G2','G2']
           inside = [1,2,3,1,2,3]
           hier_index = list(zip(outside,inside))
           hier_index = pd.MultiIndex.from_tuples(hier_index)
In [254]: hier_index
Out[254]: MultiIndex(levels=[['G1', 'G2'], [1, 2, 3]],
                       labels=[[0, 0, 0, 1, 1, 1], [0, 1, 2, 0, 1, 2]])
Out[254]: MultiIndex(levels=[['G1', 'G2'], [1, 2, 3]],
                      labels=[[0, 0, 0, 1, 1, 1], [0, 1, 2, 0, 1, 2]])
          df = pd.DataFrame(np.random.randn(6,2),index=hier_index,columns=['A','B'])
In [257]:
Out[257]:
              1 0.153661 0.167638
           G1 2 -0.765930 0.962299
              3 0.902826 -0.537909
              1 -1.549671 0.435253
           G2 2 1.259904 -0.447898
              3 0.266207 0.412580
```

Now let's show how to index this! For index hierarchy we use df.loc[], if this was on the columns axis, you would just use normal bracket notation df[]. Calling one level of the index returns the subdataframe:

```
In [260]: df.loc['G1']
Out[260]:
                           В
           1 0.153661 0.167638
           2 -0.765930 0.962299
           3 0.902826 -0.537909
In [263]: df.loc['G1'].loc[1]
Out[263]: A
               0.153661
               0.167638
          Name: 1, dtype: float64
In [265]: df.index.names
Out[265]: FrozenList([None, None])
In [266]: df.index.names = ['Group','Num']
In [267]: df
Out[267]:
                                      В
            Group Num
                    1 0.153661 0.167638
                    2 -0.765930 0.962299
                     3 0.902826 -0.537909
                     1 -1.549671 0.435253
                    2 1.259904 -0.447898
                     3 0.266207 0.412580
In [270]: df.xs('G1')
Out[270]:
                                В
            Num
            1 0.153661 0.167638
              2 -0.765930 0.962299
              3 0.902826 -0.537909
In [271]: df.xs(['G1',1])
Out[271]: A
                0.153661
                0.167638
           Name: (G1, 1), dtype: float64
In [273]: df.xs(1,level='Num')
Out[273]:
            Group
              G1 0.153661 0.167638
              G2 -1.549671 0.435253
```

IV. Missing Data

Let's show a few convenient methods to deal with Missing Data in pandas:

```
In [1]: import numpy as np
        import pandas as pd
In [9]: df = pd.DataFrame({'A':[1,2,np.nan],
                           'B':[5,np.nan,np.nan],
                          'C':[1,2,3]})
In [10]: df
Out[10]:
                  в с
          0 1.0 5.0 1
          1 2.0 NaN 2
          2 NaN NaN 3
 In [12]: df.dropna()
 Out[12]: A B C
          0 1.0 5.0 1
In [13]: df.dropna(axis=1)
Out[13]:
          С
          0 1
          1 2
          2 3
In [14]: df.dropna(thresh=2)
Out[14]:
            A B C
         o 1.0 5.0 1
         1 2.0 NaN 2
In [15]: df.fillna(value='FILL VALUE')
Out[15]:
                           вс
            1
                           5 1
                  2 FILL VALUE 2
         2 FILL VALUE FILL VALUE 3
In [17]: df['A'].fillna(value=df['A'].mean())
Out[17]: 0
              1.0
              2.0
         1
         2
             1.5
         Name: A, dtype: float64
```

1. GroupBy

The groupby method allows you to group rows of data together and call aggregate functions

```
In [33]: df
Out[33]:
             Company Person Sales
                        Sam
                              200
               GOOG
                GOOG
                      Charlie
                              120
                MSFT
                        Amy
                              340
                MSFT Vanessa
                               124
                              243
                  FB
                         Carl
                  FB
                              350
                        Sarah
```

Now you can use the .groupby() method to group rows together based off of a column name. For instance let's group based off of Company. This will create a DataFrameGroupBy object:

```
In [34]: df.groupby('Company')
Out[34]: <pandas.core.groupby.DataFrameGroupBy object at 0x113014128>
```

You can save this object as a new variable:

```
In [35]: by_comp = df.groupby("Company")
```

And then call aggregate methods off the object:

More examples of aggregate methods:

```
In [38]: by_comp.std()
Out[38]:
                       Sales
          Company
               FB 75.660426
             GOOG 56.568542
             MSFT 152.735065
In [39]: by_comp.min()
Out[39]:
                   Person Sales
          Company
                     Carl
               FΒ
                           120
             GOOG Charlie
             MSFT
                    Amy 124
```

```
In [40]: by_comp.max()
Out[40]:
                  Person Sales
          Company
          FB Sarah 350
            GOOG
                    Sam 200
            MSFT Vanessa 340
In [41]: by_comp.count()
Out[41]:
                  Person Sales
          Company
          FB 2 2
            GOOG
                      2
             MSFT 2 2
 In [42]: by_comp.describe()
Out[42]:
                            Sales
          Company
                  count 2.000000
                   mean 296.500000
                   std 75.660426
                   min 243.000000
                   25% 269.750000
                   50% 296.500000
                   75% 323.250000
                   max 350.000000
                         2.000000
                   count
                   mean 160.000000
                    std 56.568542
                   min 120.000000
             GOOG
                   25% 140.000000
                   50% 160.000000
                   75% 180.000000
                   max 200.000000
                   count 2.000000
                   mean 232.000000
                    std 152.735065
In [43]: by_comp.describe().transpose()
Out[43]: Company
                                                            FΒ
                                                                                 GOO
                                           25% 50%
                                                     75% max count mean ... 75% ma
                                 std min
                  count mean
           Sales 2.0 296.5 75.660426 243.0 269.75 296.5 323.25 350.0 2.0 160.0 ... 180.0 200.
         1 rows × 24 columns
In [44]: by_comp.describe().transpose()['GOOG']
Out[44]: count mean
                            std min 25% 50% 75% max
```

Sales 2.0 160.0 56.568542 120.0 140.0 160.0 180.0 200.0

V. Merging, Joining and Concatenating

There are 3 main ways of combining DataFrames together: Merging, Joining and Concatenating. In this lecture we will discuss these 3 methods with examples.

1. Concatenation

Example DataFrame

```
In [3]: import pandas as pd
index=[0, 1, 2, 3])
index=[4, 5, 6, 7])
index=[8, 9, 10, 11])
In [7]: df1
Out[7]:
       A B C D
     o A0 B0 C0 D0
     1 A1 B1 C1 D1
     2 A2 B2 C2 D2
     3 A3 B3 C3 D3
In [8]: df2
Out[8]:
       A B C D
      4 A4 B4 C4 D4
      5 A5 B5 C5 D5
      6 A6 B6 C6 D6
      7 A7 B7 C7 D7
In [12]: df3
Out[12]:
           В
              С
                D
        A8
          B8
             C8
                D8
        A9 B9 C9 D9
      10 A10 B10 C10 D10
      11 A11 B11 C11 D11
```

Concatenation basically glues together DataFrames. Keep in mind that dimensions should match along the axis you are concatenating on. You can use **pd.concat** and pass in a list of DataFrames to concatenate together:

```
In [10]: pd.concat([df1,df2,df3])
Out[10]:
              Α
                  В
                      С
                          D
             A0
                 B0
                     C0
                         D0
             Α1
                 B1
                     C1
                         D1
             A2
                 B2
                     C2
                         D2
             АЗ
                 B3
                     C3
                         D3
             A4
                 B4
                     C4
                         D4
             A5
                 B5
                     C5 D5
             A6
                 B6
                     C6
                         D6
             A7
                 B7
                     C7
                         D7
             A8
                 B8
                     C8
                         D8
             A9
                 B9
                     C9
                         D9
          10 A10 B10 C10 D10
          11 A11 B11 C11 D11
In [18]: pd.concat([df1,df2,df3],axis=1)
Out[18]:
              Α
                  В
                      С
                           D
                               Α
                                   В
                                       С
                                            D
                                                    В
                                                        С
                                                            D
                                                Α
          0
             A0
                  B0
                      C0
                          DO NaN NaN NaN NaN NaN NaN NaN
             A1
                  B1

             АЗ
                  ВЗ
                      C3
                          D3 NaN NaN NaN NaN
                                             NaN NaN NaN
          4 NaN NaN NaN NaN
          5 NaN
                NaN
                    NaN NaN
                              A5
                                   В5
                                      C5
                                           D5
                                             NaN
                                                  NaN NaN
          6 NaN
                NaN NaN NaN
                              A6
                                   B6
                                      C6
                                           D6
                                             NaN NaN NaN
          7 NaN
                NaN NaN NaN
                              A7
                                  B7
                                      C7
                                           D7 NaN NaN NaN NaN
          8 NaN NaN
                    NaN NaN NaN NaN NaN
                                               A8
                                                   B8
                                                       C8
                                                            D8
          9 NaN NaN
                     NaN NaN NaN NaN NaN
                                               A9
                                                   B9
                                                       C9
                                                            D9
          10 NaN NaN NaN NaN NaN NaN NaN A10 B10 C10 D10
         11 NaN NaN NaN NaN NaN NaN NaN NaN A11 B11 C11 D11
```

2. Merging

Example DataFrame

```
In [29]: left
Out[29]:
       A B key
     o A0 B0
     1 A1 B1
          K1
     2 A2 B2 K2
     3 A3 B3 K3
In [30]: right
Out[30]:
       C D key
     0 C0 D0
          K0
     1 C1 D1
          K1
     2 C2 D2 K2
     3 C3 D3 K3
```

The merge function allows you to merge DataFrames together using a similar logic as merging SQL Tables together. For example:

```
In [35]: pd.merge(left,right,how='inner',on='key')
Out[35]:
            A B key C D
         o A0 B0 K0 C0 D0
         1 A1 B1 K1 C1 D1
         2 A2 B2 K2 C2 D2
         3 A3 B3 K3 C3 D3
```

Or to show a more complicated example:

```
right = pd.DataFrame({'key1': ['K0', 'K1', 'K1', 'K2'],
                                          'key2': ['K0', 'K0', 'K0', 'K0'],
'C': ['C0', 'C1', 'C2', 'C3'],
'D': ['D0', 'D1', 'D2', 'D3']})
 In [39]: pd.merge(left, right, on=['key1', 'key2'])
 Out[39]:
              A B key1 key2 C D
           o A0 B0
                     K0
                         K0 C0 D0
                         K0 C1 D1
           1 A2 B2
                     K1
                         K0 C2 D2
           2 A2 B2 K1
 In [40]: pd.merge(left, right, how='outer', on=['key1', 'key2'])
 Out[40]:
               A
                   B key1 key2
                                 C
                                     D
              A0
                  B0
                       K0
                           K0
                                CO
                                    D0
           1
              A1
                   B1
                       K0
                           K1 NaN NaN
           2
              A2
                  B2
                       K1
                           K0 C1
                                    D1
           3
              A2
                  B2
                       K1
                           K<sub>0</sub>
                                C2

          1
             A2
                  B2
                      K1
                           K0 C2 D2
          3 NaN NaN K2 K0 C3 D3
 In [42]: pd.merge(left, right, how='left', on=['key1', 'key2'])
 Out[42]:
              A B key1 key2
                              С
                                  D
                                  D0
           o A0 B0
                     K0
                         K0
                             C0
           1 A1 B1
                     K0
                         K1 NaN NaN
                    K1
           2 A2 B2
                        K0
                                  D1
                             C1
           3 A2 B2
                         K0 C2
                                  D2
                    K1
                    K2 K1 NaN NaN
           4 A3 B3
```

3. Joining

Joining is a convenient method for combining the columns of two potentially differently-indexed DataFrames into a single result DataFrame.

```
In [47]: left.join(right)
Out[47]: A B C D
     KO AO BO CO DO
     K1 A1 B1 NaN NaN
     K2 A2 B2 C2 D2
In [48]: left.join(right, how='outer')
Out[48]:
           B C D
      K0 A0 B0 C0 D0
      K1
        A1
          B1 NaN NaN
      K2 A2 B2 C2 D2
      K3 NaN NaN C3 D3
```

VI. Operations

There are lots of operations with pandas that will be really useful to you, but don't fall into any distinct category. Let's show them here in this lecture:

1. Info on Unique Values

2. Selecting Data

3. Applying Functions

```
In [58]: def times2(x):
              return x*2
 In [59]: df['coll'].apply(times2)
 Out[59]: 0
               4
          1
          2
               6
               8
          Name: col1, dtype: int64
In [60]: df['col3'].apply(len)
Out[60]: 0
              3
              3
         1
         2
              3
         Name: col3, dtype: int64
In [61]: df['col1'].sum()
Out[61]: 10
```

Permanently Removing a Column

```
In [62]: del df['coll']

In [63]: df

Out[63]: col2 col3

0 444 abc

1 555 def

2 666 ghi

3 444 xyz
```

Get column and index names:

```
In [64]: df.columns
Out[64]: Index(['col2', 'col3'], dtype='object')
In [65]: df.index
Out[65]: RangeIndex(start=0, stop=4, step=1)
```

Sorting and Ordering a DataFrame:

Find Null Values or Check for Null Values

Filling in NaN values with something else:

```
In [3]: import numpy as np
  'col3':['abc','def','ghi','xyz']})
          df.head()
   Out[6]:
             col1 col2 col3
           o 1.0 NaN
                      abc
           1 2.0 555.0
                      def
           2 3.0 666.0 ghi
           3 NaN 444.0 xyz
   In [7]: df.isnull()
   Out[7]:
              col1 col2 col3
           0 False True False
            1 False False False
           2 False False False
            3 True False False
In [8]: df.dropna()
Out[8]:
           col1 col2 col3
        1 2.0 555.0
                     def
         2 3.0 666.0 ghi
In [9]: df.fillna('FILL')
Out[9]:
           col1 col2 col3
            1 FILL
                    abc
         0
             2 555
                     def
             3 666
                     ghi
         3 FILL 444 xyz
       df = pd.DataFrame(data)
        In [90]: df
        Out[90]:
                   A B C D
                0 foo one x 1
                2 foo two x 2
                3 bar two y 5
                4 bar one x 4
                5 bar one y 1
        In [91]: df.pivot_table(values='D',index=['A', 'B'],columns=['C'])
        Out[91]:
                    С
                    В
                   one 4.0 1.0
                   two NaN 5.0
                   one 1.0 3.0
                   two 2.0 NaN
```

VII. Data Input and Output

This notebook is the reference code for getting input and output, pandas can read a variety of file types using its pd.read_ methods. Let's take a look at the most common data types:

```
In [1]: import numpy as np import pandas as pd
```

1. CSV

CSV Input

CSV Output

```
In [24]: df.to_csv('example.csv',index=False)
```

2. Excel

Pandas can read and write excel files, keep in mind, this only imports data. Not formulas or images, having images or macros may cause this read_excel method to crash.

Excel Input

```
In [35]: pd.read_excel('Excel_Sample.xlsx',sheetname='Sheetl')

Out[35]:

a b c d

0 0 1 2 3

1 4 5 6 7

2 8 9 10 11

3 12 13 14 15
```

Excel Output

VIII. Exersises

1. Sales

Fill in the TODO cells in sales.ipynb notebook.

- ✓ Fix column datatypes.
- ✓ Drop if duplicated or null.
- ✓ Sanity check for value ranges and to check assumptions.
- ✓ Use regular expression and lambda function to parse data.

2. Job Market

Given the job market data in csv file. Create your own jupyter notebook and explore the data by:

- ✓ Load the data using Pandas.
- ✓ Visualize top 10 first rows
- ✓ Fix column datatypes.
- ✓ Check and clean the data.
